The events listed above meet at least one of the following criteria:

1) reported in at least two observers' reports.
2) visually analyzed with definiteness rating $=5$ on submitted charts
3) reported by overseas observers with high definiteness rating

| Observer | Code | Station(s) Monitored |
| :--- | :--- | :--- |

| $3+$ | $>125$ |

Editor's Note: A review of the Solar Bulletin distribution list has identified many former observers/contributors which have not submitted reports for many months. It is the policy of the AAVSO Solar Division to provide all contributing observers a monthly copy of the Solar Bulletin. Several solar research institutions, professional scientists, and observers allied with solar observing groups who share reports with the AAVSO also receive complimentary issues of the Solar Bulletin. In an effort to minimize publication expenses, observers who have not contributed reports for the past year will be removed from the distribution list and this issue will be their last and only notice.

Note to Observers: All observers are reminded to send their monthly reports directly to Joseph Lawrence, Solar Division Chairman, as early as possible each month. Only observer reports received by the 10 th of the month will be included in the relative sunspot count computation. Reports received after the 10 th will be archived in the sunspot database. Please write legibly and carefully review your reports for inaccuracies and omissions. Most notably, a handful of sunspot reports were received in January which omitted the universal time of observation and numerous Wolf number computation mistakes were identified during data entry.

The graph above shows 10.7 cm flux plotted against Zurich sunspot numbers computed from observations of seven AAVSO sunspot observers who count according to the Zurich system. The Zurich reduction formula was used to reduce their counts to true Zurich Relative Sunspot Numbers, RZ. AAVSO Sunspot observer, Tom Lizak, prepared the graph

Len Anderson, A-91, made the above recording of two SIDs. Notice that his chart reads from right to left unlike the others. Being in West Australia he can record SIDs in the early Universal Time day that other AAVSO observers cannot detect because their propagation paths are in darkness Thanks to his recordings AAVSO now has 24-hour coverage. His station is located about 1000 km south of the NWC transmitter in Northwest Cape. Last month he recorded inverted SIDs but this month they are normal enhancements of the signal.

Two charts above are by Jerry Winkler, A-50. The top chart shows an unusually large SES that lasts for three hours. The 30-minute rise to maximum is also unusual. Most SESs rise to maximum in about 3 minutes like A-50's second chart that shows an event of equal intensity that lasts only about 45 minutes. Below is a recording of the same 3-hour SID as recorded by Jim Mandaville, A-90 who normally records NPM in Hawaii. He had switched to NAA because NPM was off the air for maintenance that day. His chart also shows the event lasting 3 hours and taking 30 minutes to rise to maximum.

Another chart by A- 90 shows an interesting SID on 26 January soon after the sunrise pattern ended. The rise to maximum starts out inverted but after about one minute it reverses and rises to maximum in an additional 4 minutes. It is a short duration SID that ends 30 minutes after it started. A-90 has been recording NPM since last summer and the SESs have been normal enhancements. January was the first month partially inverted SIDs were found. This is surprising considering the long propagation path from Arizona to Hawaii. Inversions are usually found on short paths.
