Editor's Note: All sunspot observers are requested to include their observer code listed above on monthly reports and all correspondence with the AAVSO Solar Division. All individual observations are referenced by your observer code in the sunspot database. This will allow more efficient searches of data and recognition of individual contributions.

Many thanks to the observers who used the SUNKEY data entry program to submit their monthly reports. There were problems noted with the program. It is expected that a more user-friendly version of the program be available in the next couple of months and it will eliminate these problems.

# Sudden Ionospheric Disturbances Recorded During May <br> Prepared by <br> Casper H. Hossfield 

The enlarged section of a chart above shows a recording of the gamma ray burst at 1022 UT on 27 August 1998. It was made by A-52 in South Africa and shows an SES (sudden enhancement of signal) of VLF (very low frequency) radio station NWC at Northwest Cape in West Australia on 19.8 kHz . The enlargement is taken from a multiplexed chart like the chart below that recorded a solar flare on 27 February 1999. Here three signals are recorded and the flare enhanced all three. The flare that caused these enhancements was much more intense than the gamma ray burst that caused only a very small enhancement of NWC's signal. Although it was small it was nevertheless very definite and occurred at exactly the right time on a clean interference free chart. This is the only recording of the gamma ray burst by an amateur that I know of. A recording of the burst as an SES by a professional observatory recording NPM in Hawaii was published in Science and also in Sky \& Telescope magazine. A-52's success in recording the gamma ray burst is due to the excellent receivers that make the multiplexed charts. The receiver is a superhetrodyne designed by Domenic Toldo who operates station A-52 for Danie Overbeek. It is a true superhetrodyne that down-converts the VLF signal to a lower IF (intermediate frequency) signal, in this case 1359 Hz . The IF frequency is in the lower audible range so a second detector is not needed to hear the signal. All other superhetrodyne receivers I know of in use by AAVSO observers use a VLF converter that up-converts into a commercial communications receiver. The inherent selectivity advantage of a superhetrodyne receiver is lost when the VLF signal is up-converted. Domenic has kindly supplied a detailed schematic for his receiver that is shown below. If you are interested in this receiver and would like to know more about it please contact me at my new e-mail address, < CapAAVSO@aol.com > or my new Fax number, 973853 2588. My postal address remains the same. CHH
